

Apply Canny Edge Detection

Canny edge detection is a multi-stage algorithm that detects a wide range of edges in images. It's known for its ability to detect strong and weak edges while suppressing noise.

✓ Apply Image Erosion

Image erosion is a morphological operation that shrinks or thins objects in a binary image. It's often used to remove small anomalies, detach unwanted connections, or to prepare images for other operations. Like dilation, it uses a structuring element (kernel) to determine the effect.

◆ Gemini

```
import cv2
from google.colab.patches import cv2_imshow

# Define a kernel for erosion (e.g., a 5x5 rectangular kernel)
kernel_erosion = cv2.getStructuringElement(cv2.MORPH_RECT, (5, 5))

# Apply erosion to the grayscale image
eroded_img = cv2.erode(gray_img, kernel_erosion, iterations=1)

cv2_imshow(eroded_img)
cv2.imwrite('eroded_image.jpg', eroded_img)

print("Eroded image displayed and saved as 'eroded_image.jpg'.")
```

Eroded image displayed and saved as 'eroded_image.jpg'.
